# What did pre-impact simulations suggest?

A sphere can overestimate the value of  $\beta$  by 10 – 20% compared to the DART spacecraft geometry

3 spheres better approximates DART spacecraft geometry, but still is an overestimate...

(a) Weak target (Spheral)

(b) Weak target (iSALE)

Figure adapted from Owen et al. 2022

# Impact using the DART Spacecraft Geometry

Full Spacecraft CAD Model with 580 kg mass – does not model Xe and hydrazine

Highest resolution = 7 cm

Dimorphos Density = 2.3 g/cc

Granular Material with 1 kPa cohesive and tensile strength (using GEO model in CTH) with Johnson-Cook Damage and coefficient of internal friction of 0.7

Impact Speed = 6.15 km/s

# Impact Timeline in Simulations

t = 0 sec

t = 0.025 sec

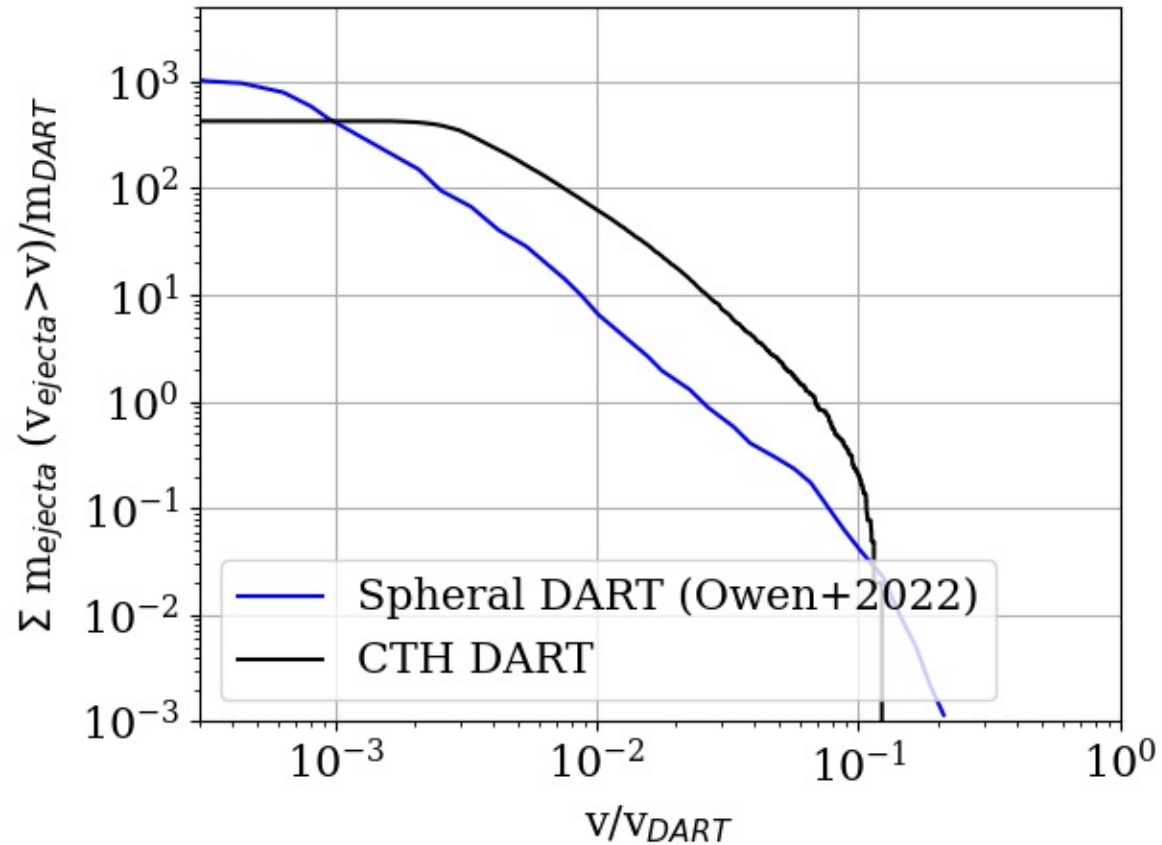

t = 0.05 sec

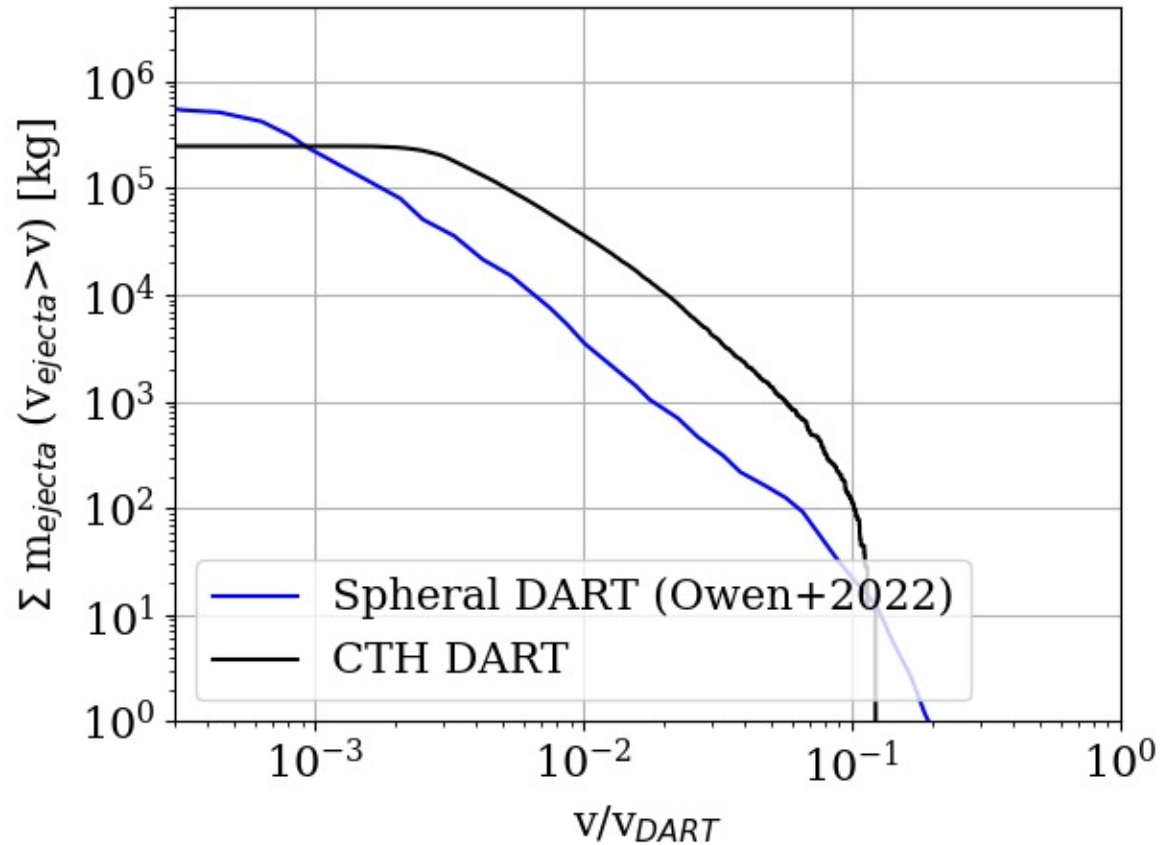

t = 0.1 sec

The evolution of the crater and the ejecta is influenced by the spacecraft shape

# Ejecta Cone and Properties

# Ejecta Cone and Properties

Ejecta is still being produced at these early times...

# Crater Properties at 100msec

At these times, the crater is still growing...

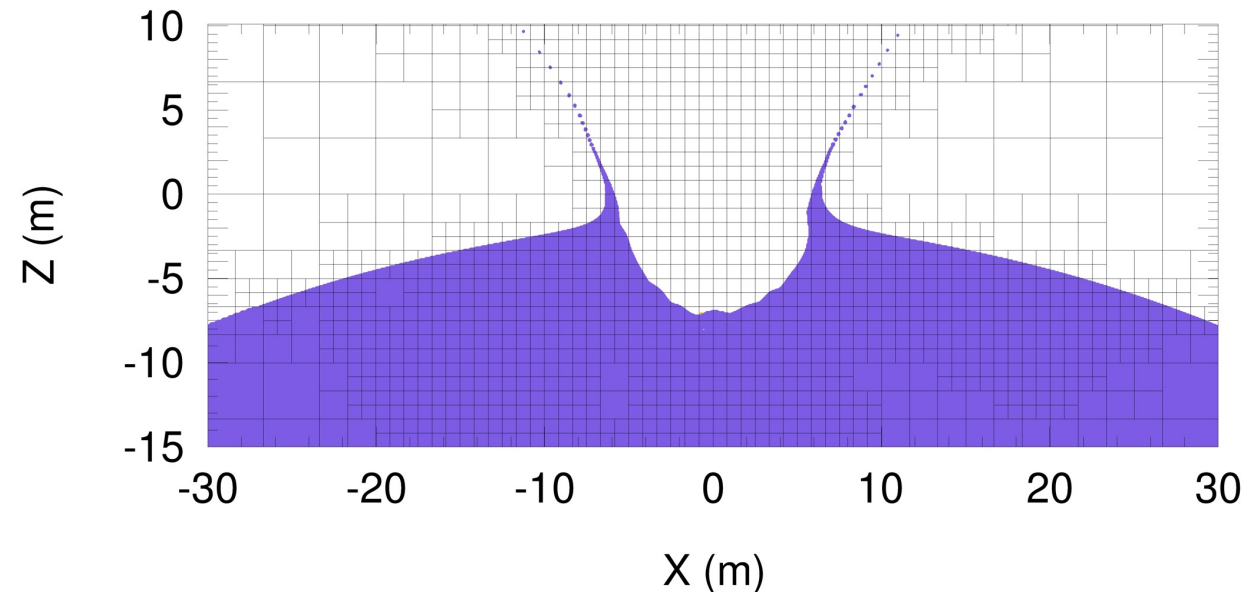

Not clear from this analysis if the side lobes will merge into the central crater or not...

At this time using this method, approximate crater size is:

Side craters: ~ 4 meters

Central crater: ~ 10 meters

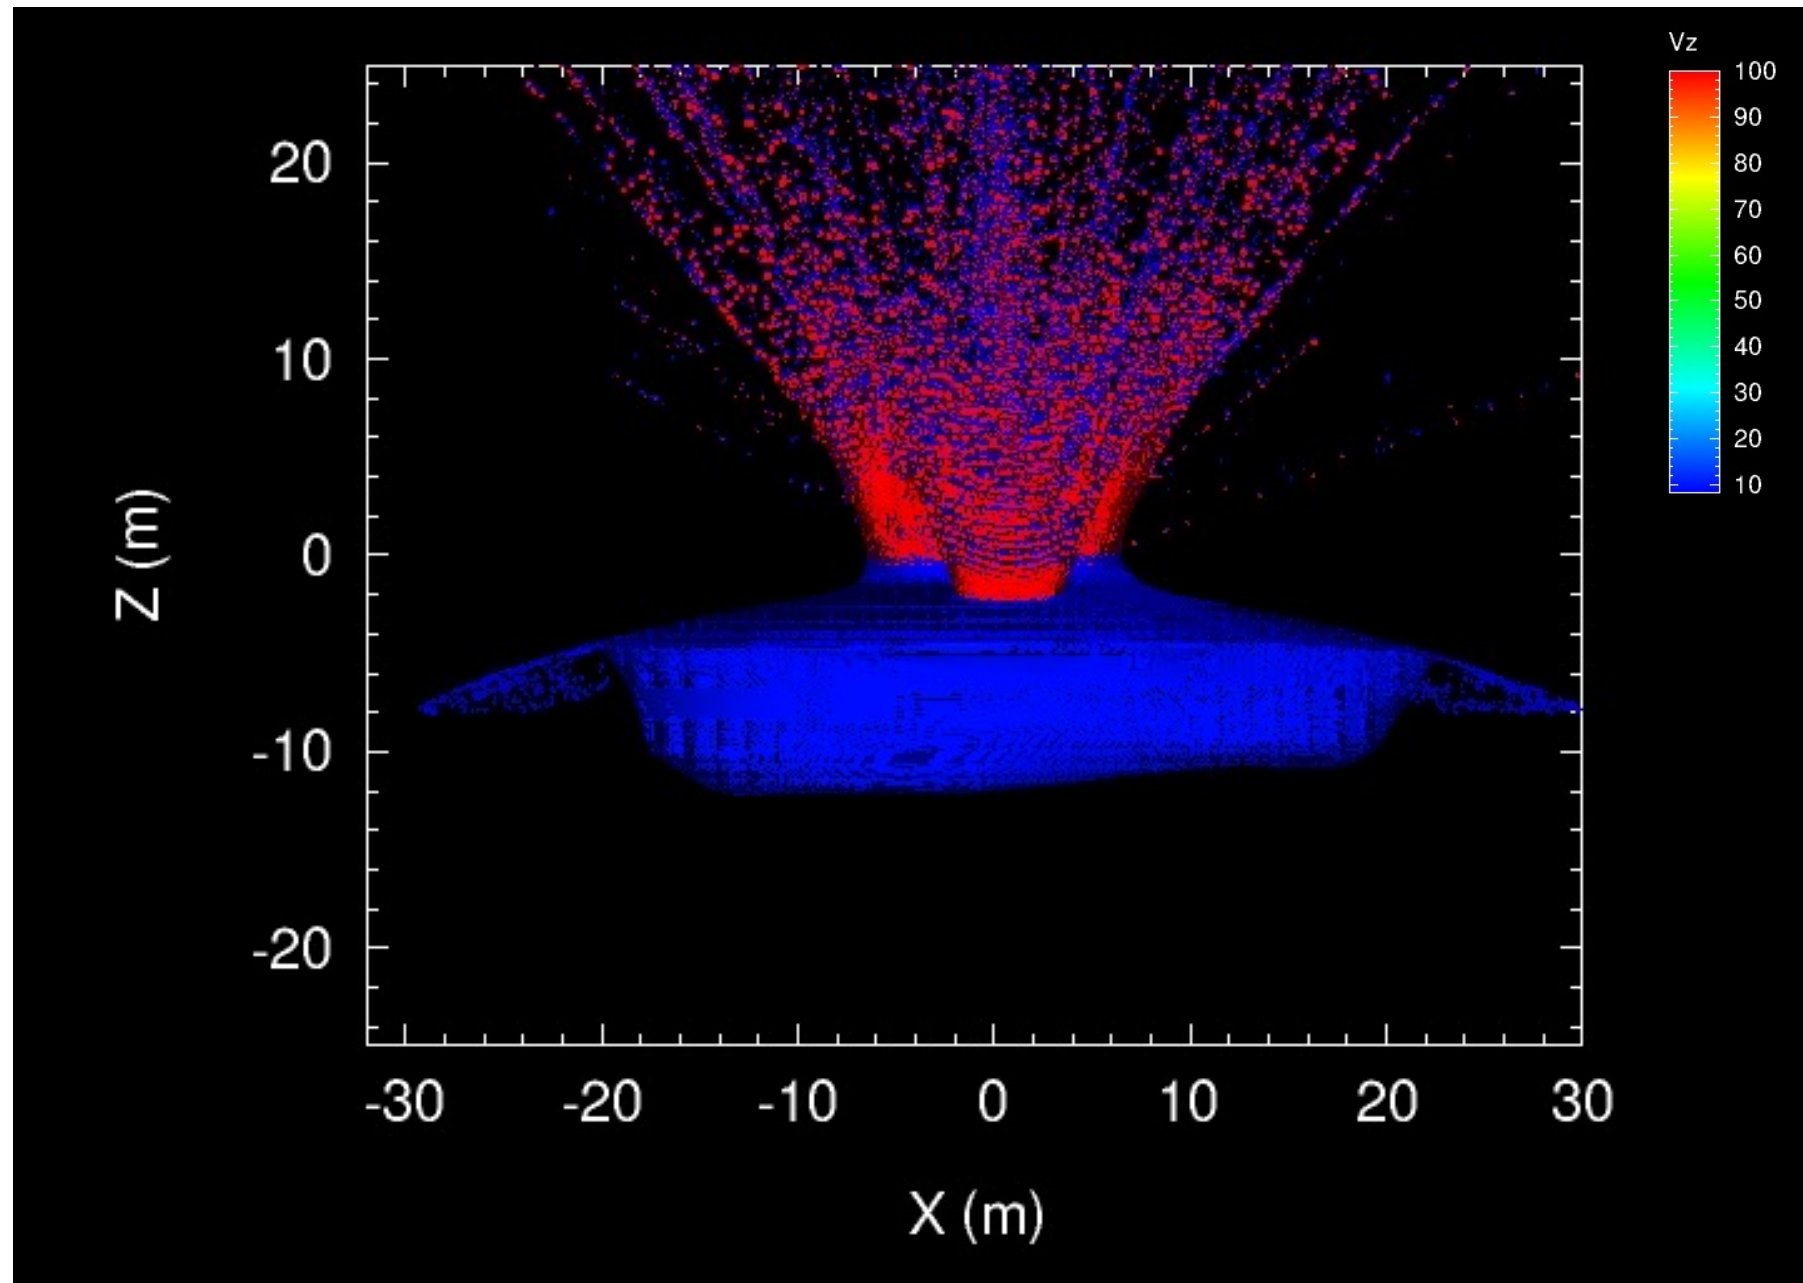

Total crater width ~ 20 meters

# Crater Properties at 100msec

But we can use velocity thresholds using the escape velocity of the system as the threshold...

Expands the final crater size up to **~40 meter** diameter and the crater lobes have merged.

# Momentum Transfer - $\beta$

Adjusting  $\beta$  for density with the results in Cheng et al. 2023, we see that the spacecraft impacting into a 1kPa target produces too high of a  $\beta$  value...

# Momentum Transfer - $\beta$

Adjusting  $\beta$  for density with the results in Cheng et al. 2023, we see that the spacecraft impacting into a 1kPa target produces too high of a  $\beta$  value...

# General Takeaways & Future Work

Simulations using the spacecraft impacting into a moderately weak homogeneous 1kPa target result in  $\beta$  values in excess of what was observed with DART.

The inclusion of rubble pile structures will decrease the value of  $\beta$ , however it is unclear if that alone will be enough to reach the range of observed values without increasing strength.
